Key indicators: single-crystal X-ray study; $T = 183$ K; mean $\sigma(C-C) = 0.008$ Å;
disorder in main residue; R factor = 0.024; wR factor = 0.057; data-to-parameter
ratio = 17.8.

The title binuclear compound, $[W_2Cl_6(NO)_2(C_{10}H_{22}P_2)_3]$, contains two W atoms which are bridged by a bis(diethylphosphino)ethane (depe) ligand. The seven-coordinated tungsten(II) centres display distorted pentagonal-bipyramidal geometries with *trans* nitrosyl and chloride ligands. The title molecule lies on a crystallographic inversion centre. The ethane group of the non-bridging depe ligand is positionally disordered, with site-occupancy factors of 0.63 and 0.37. In the crystal structure, the binuclear molecules are linked by weak intermolecular C–H···O and C–H···Cl interactions. In addition, weak intramolecular C–H···Cl interactions are also present.

Comment

The mononuclear compound $[W(Cl)_2(NO)(dmpe)_2](Cl)$ was previously obtained by the reaction of $[W(Cl)_3(NO)(NCCH_3)_2]$ with 2.5 equivalents of dmpe [1,2-bis(dimethylphosphino)ethane] at room temperature in tetrahydrofuran (Avramović *et al.*, 2008). The synthesis of the analogous compound $[W(Cl)_2(NO)(depe)_2](Cl)$ was also attempted by the same procedure using the bidentate ligand depe [1,2-bis(diethylphosphino)ethane]. Presumably because of steric factors, only the binuclear compound $[W(Cl)_3(NO)(depe)]_2(\mu\text{-}depe)$ was formed instead of the expected mononuclear compound.

The title compound consists of two metal units bridged by a depe ligand (see: Campbell *et al.*, 1985; Han & Coucouvanis, 2002; Zeng *et al.*, 1994; Landau *et al.*, 1999). Both tungsten centers are crystallographically equivalent since the molecule lies on a crystallographic inversion center (Fig. 1). The geometry at tungsten(II) is very similar to that in $[W(Cl)_2(NO)(dmpe)_2](Cl)$ with a distorted pentagonal bipyramidal coordination. A second chloride ligand takes the place of one phosphorus in $[W(Cl)_2(NO)(dmpe)_2](Cl)$ to complete the equatorial plane of the polyhedron (P1, P2, P3, Cl1 and Cl2). The five equatorial bond angles, in the range $70.8 - 73.5^\circ$, are close to the theoretically average angle of 72° . It is worth noting that the five equatorial atoms are not completely coplanar. Atoms Cl1 and Cl2 deviate from the P1—P2—P3 plane, toward the third chloride atom Cl3, by 0.303 (2) and 0.543 (2) Å, respectively. Nevertheless, this geometry is clearly different to that observed for the related compound $Mo(Cl)_3(NO)(PMo_3)_3$, for which the coordination polyhedron is described as a capped-octahedron (Carmona *et al.*, 1989).

All the chloride ligands are engaged in hydrogen bonding, with atoms Cl1 and Cl2 involved in ten intramolecular interactions with CH_2 hydrogen atoms within the dimer, and atom Cl3 (*trans* to the nitrosyl group) in one weak intermolecular interaction with the methyl hydrogen atom H10A (Fig. 2, Table 1). The C10···Cl3 donor-acceptor distance of 3.726 (7) Å represents a rather weak interaction of this type (Desiraju & Steiner, 1999). In addition, the binuclear complexes are linked by two weak intermolecular C—H···O hydrogen bonds between the nitrosyl oxygen atom and the hydrogen atoms of the disordered ethane bridge.

Experimental

$[W(Cl)_3(NO)(depe)]_2(\mu\text{-}depe)$ was prepared from the complex $[W(Cl)_3(NO)(CH_3CN)_2]$. The latter is easily synthesized by the reaction of $W(Cl)_6$ with NO gas in dichloromethane in the presence of acetonitrile at room temperature, according to a literature procedure (Bencze & Kohán, 1982; Hunter & Legzdins, 1984). 5.00 g (12.6 mmol) of WCl_6 and 1.32 ml (25.2 mmol) of acetonitrile were dissolved in 180 ml of dichloromethane in a 500 ml three-necked flask. Nitric oxide was passed through the solution, which was stirred at room temperature until the dark purple colour of the solution turned to the light green precipitate after *ca* 1 h. The volume of the final mixture was reduced to 50 ml *in vacuo* and the mixture

supplementary materials

was then cooled to 0°C for 15 min. The precipitate was isolated by filtration and the collected solid was then washed first with cold dichloromethane (2×10 ml at 0°C) and then with hexane (4×20 ml) at room temperature. Final drying of the solid under vacuum for 18 h afforded the yellow-green $[W(Cl)_3(NO)(CH_3CN)_2]$ compound. 0.200 g (0.497 mmol) of $[W(Cl)_3(NO)(NCCH_3)_2]$ was dissolved in 20 ml of tetrahydrofuran in a Young tap Schlenk and the depe ligand (0.29 ml, 1.243 mmol) was syringed into the solution. The solution was stirred at room temperature for 24 h, then filtered and the solvent removed under vacuum. The resulting solid was crystallized from dichloromethane at room temperature and gave light-green crystals of the title compound.

Yield: 0.266 g (85%).

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R-factor wR and goodness of fit S are based on F^2 , conventional R-factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on F^2 are statistically about twice as large as those based on F , and R-factors based on ALL data will be even larger.
